Project Design Phase

Proposed Solution Template

Project Detail	Value
Date	21 October 2026
Team ID	Individual Project
Project Name	StaffSync – Modern Human Resource Management System
Maximum Marks	2 Marks

Proposed Solution

S. No.	Parameter	Description
1	Problem Statement (Problem to be solved)	Organizations may manage employee records, attendance, leave applications, announcements, and staff information through separate spreadsheets, emails, or manual processes. This can make records harder to maintain, delay leave decisions, reduce visibility into attendance and request status, and complicate access control for sensitive employee information.
2	Idea / Solution Description	StaffSync is a MERN-stack Human Resource Management System built around three user roles: Employee, Manager, and HR. The React frontend communicates with a Node.js/Express REST API, and MongoDB stores user and HR-related records. The system brings together authentication, employee and manager management, attendance tracking, leave application and review, announcements, training, performance information, dashboards, and notifications, according to each user's permissions.
3	Novelty / Uniqueness	• Role-specific workflows for Employees, Managers, and HR in one application. • Centralized employee, attendance, and leave records. • Leave application and authorized approval/rejection workflow with status visibility. • JWT-based authentication and role-based access control as part of the application design. • Modular MERN architecture that can be extended as additional verified requirements are implemented.
4	Social Impact / Customer Satisfaction	• Reduces reliance on disconnected manual HR records. • Helps employees view attendance and leave status more transparently. • Helps HR and managers access relevant information for their authorized responsibilities. • Supports clearer internal communication through announcements and notifications. • Aims to improve consistency of routine HR workflows; actual impact should be evaluated through user feedback and testing.
5	Business Model (Revenue Model)	StaffSync is currently presented as an individual academic/capstone project rather than a commercial product with a confirmed revenue model. If developed for organizational use in the future, possible models could include a subscription per organization or per active employee, or a licensed deployment with support. These are future possibilities, not current implemented features.
6	Scalability of the Solution	• Modular frontend, API, and database layers provide a foundation for future enhancements. • Pagination, indexes, and efficient database queries can support larger record sets as required. • The application can be deployed to suitable hosting and database services after environment configuration and testing. • Potential future extensions include payroll, biometric attendance integration, audit reporting, and third-party HR tools; these should be treated as future scope unless implemented.

Implementation Scope Note

This proposed solution reflects StaffSync's stated project scope. It does not claim that payroll, biometric integration, subscription billing, video calls, AI features, or third-party integrations are currently implemented. Before final submission, confirm that each described feature matches the latest source code and can be demonstrated in the running application.
